# **Kinetikus deutérium izotópeffektus**

# E1 vagy E2 típusú az elimináció?

## How to distinguish E1 from E2: kinetic isotope effects

We have told you what sorts of starting materials and conditions favour E1 or E2 reactions, but we haven't told you how we know this. E1 and E2 differ in the order of their rate equations with respect to the base, so one way of finding out if a reaction is E1 or E2 is to plot a graph of the variation of rate with base concentration. But this can be difficult with E1 reactions because the base (which need be only very weak) is usually the solvent. More detailed evidence for the differences between reaction mechanisms comes from studying the rates of elimination in substrates that differ only in that one or more of the protons have been replaced by deuterium atoms. These differences are known as **kinetic isotope effects**.

Up to now you have probably (and rightly) been told that isotopes of an element (that is, atoms that differ only in the number of neutrons their nuclei contain) are chemically identical. It may come as a surprise to find that this is not quite true: isotopes do differ chemically, but

this difference is only significant for hydrogen—no other element has one isotope twice as massive as another! Kinetic isotope effects are the changes in rate observed when a ( $^1\text{H}$ ) hydrogen atom is replaced by a ( $^2\text{H}$ ) deuterium atom in the same reaction. For any reaction, the kinetic isotope effect is defined as

$$\text{KIE} = \frac{k_{\text{H}}}{k_{\text{D}}}$$

rate with substrate containing  $^1\text{H}$

rate with substrate containing  $^2\text{H}$

Changing H for D can affect the rate of the reaction only if that H (or D) is involved in the rate-determining step. The theoretical maximum is about 7 for reactions at room temperature in which a bond to H or D is being broken. For example, the rates of these two eliminations can be compared, and  $k_{\text{H}}/k_{\text{D}}$  turns out to be 7.1 at 25 °C.

### zero point energy and kinetic isotope effects

# Benzol nitrálásakor melyik a sebességmeghatározó lépés?

Kísérleti eredmény:  $k_H/k_D=1.0$

És mi a helyzet, ha fenolt jódozunk lúgos körülmények között?

Kísérleti eredmény:  $k_H/k_D=4.1$

# **Inverz kinetikus deutérium izotópeffektus**

$$r = k[\text{XH}^{\oplus}]$$

$$[\text{XH}^{\oplus}] = K[\text{H}^{\oplus}][\text{X}]$$

$$r = Kk[\text{H}^{\oplus}][\text{X}]$$

**Kísérleti tapasztalat: a reakció gyorsabb D<sub>2</sub>O-ban, mint H<sub>2</sub>O-ban**

**Magyarázat: D<sub>3</sub>O<sup>+</sup> erősebb sav D<sub>2</sub>O-ban, mint a H<sub>3</sub>O<sup>+</sup> H<sub>2</sub>O-ban**

$$k(\text{H}_2\text{O})/k(\text{D}_2\text{O}) = 1.0/2.5$$

# **Aktiválási entrópia**

az aktiválási entrópia és a Hammett-féle  $\rho$  paraméter kombinálható

$$\rho = -4.1$$

$$\Delta S^\ddagger = -48 \text{ J mol}^{-1} \text{ K}^{-1}$$

● The Hammett reaction constant  $\rho$  measures the *sensitivity* of the reaction to electronic effects.

- A *positive*  $\rho$  value means *more* electrons in the transition state than in the starting material
- A *negative*  $\rho$  value means *fewer* electrons in the transition state than in the starting material

● The meaning of Hammett  $\rho$  values

This then is the full picture. You should not, of course, learn these numbers but you need an idea of roughly what each group of values means. You should see now why it is unimportant whether the Hammett correlation gives a good straight line or not. We just want to know whether  $\rho$  is + or – and whether it is, say, 3 or 6. It is meaningless to debate the significance of a  $r$  value of 3.4 as distinct from one of 3.8.

# Sav-bázis katalízis

### specific acid catalysis

### specific base catalysis

# Specifikus savkatalízis

**Kísérleti megfigyelések: (i) a reakciósebesség fordítva arányos a pH-val (a katalitikus hatás jelentős, ha a sav  $\text{pK}_a$  értéke kisebb, mint a szubsztraté), (ii) a reakció gyorsabban megy  $\text{D}_2\text{O}$ -ban, mint  $\text{H}_2\text{O}$ -ban (inverz deutérium izotópeffektus)**

## ● Summary of features of specific acid catalysis

1. Only  $\text{H}_3\text{O}^+$  is an effective catalyst; pH alone matters
2. Usually means rate-determining reaction of protonated species
3. Effective only at pHs near or below the  $\text{p}K_{\text{aH}}$  of the substrate
4. Proton transfer is not involved in the rate-determining step
5. Only simple unimolecular and bimolecular steps—moderate + or  $-\Delta S^\ddagger$
6. Inverse solvent isotope effect  $k(\text{H}_2\text{O}) < k(\text{D}_2\text{O})$

# Specifikus báziskatalízis

**Kísérleti megfigyelések: (i) a reakciósebesség egyenesen arányos a pH-val (a katalitikus hatás jelentős, ha a szubsztrát  $pK_a$  értéke kisebb, mint a bázisé), (ii) a reakció gyorsabban megy  $D_2O$ -ban, mint  $H_2O$ -ban (inverz deutérium izotópeffektus)**

## ● Summary of features of specific base catalysis

1. Only  $\text{HO}^-$  is an effective catalyst; pH alone matters
2. Usually means rate-determining reaction of deprotonated species
3. Effective only at pHs near or above the  $\text{p}K_a$  of the substrate
4. Proton transfer is not involved in the rate-determining step, unless C–H bonds are involved
5. Only simple unimolecular and bimolecular steps—moderate + or  $-\Delta S^\ddagger$
6. Inverse solvent isotope effect  $k(\text{H}_2\text{O}) < k(\text{D}_2\text{O})$

# Általános savkatalízis

## specific acid-catalysed acetal hydrolysis

## general acid-catalysed acetal hydrolysis

### specific acid catalysis

### general acid catalysis

## ● Summary of features of general acid catalysis

1. Any acid is an effective catalyst; pH also matters
2. Proton transfer is involved in the rate-determining step
3. Effective at neutral pHs even if above the  $pK_{aH}$  of the substrate
4. Catalyst often much too weak an acid to protonate reagent
5. Catalyst adds proton to a site that is becoming more basic in the rate-determining step
6. Some other bond-making or bond-breaking also involved unless proton is on carbon
7. Often termolecular rate-determining step: large  $-\Delta S^\ddagger$
8. Normal kinetic isotope effect  $k(H) > k(D)$

# Általános báziskatalízis

**Kísérleti megfigyelések: (i) jobban megy a reakció, ha nő a pH, de leggyorsabb semleges pH-nál, (ii) a reakció gyorsabban megy ROH-val, mint ROD-vel ([normál] deutérium izotópeffektus), (iii) hatalmas entrópiacsökkenés**

## ● Summary of features of general base catalysis

1. Any base is an effective catalyst; pH also matters
2. Proton transfer is involved in the rate-determining step
3. Effective at neutral pHs even if below the  $pK_a$  of the substrate
4. Catalyst often much too weak a base to deprotonate reagent
5. Catalyst removes proton, which is becoming more acidic in the rate-determining step
6. Some other bond-making or bond-breaking also involved unless proton is on carbon
7. Often termolecular rate-determining step: large  $-\Delta S^\ddagger$
8. Normal kinetic isotope effect  $k(H) > k(D)$
